INTRODUCTION
Embryonic development is a complex process from the time of fertilisation to the formation of cells, tissues and organs. In early pregnancy, each body organ (system) has a critical period of organogenesis. Interference during this early pregnancy with intrinsic and extrinsic factors (i.e. parental and multifactorial effects) may lead to different types of birth defects.¹⁻³ Birth defects are one of the major causes of infant and child mortality, morbidity, and long-term disability.⁴⁻⁵ The term ‘birth defects’ refer to any morphological, functional, behavioural, and metabolic defects that develop during the organogenesis period and present at birth or detected later in life.² Birth defects may be caused by genetic, chromosomal, environmental, and multifactorial effects, as well as micronutrient deficiencies or unknown etiological agents.⁶⁻⁷

Abstract

Objective: To determine the characteristics and background of mothers who delivered neonates with birth defects.

Methods: A retrospective study was used by evaluating the medical records of patients with birth defects in Dr. Cipto Mangunkusumo Hospital during the period between September 2014 to June 2016.

Results: A total of 67 (1.85%) out of 3,619 infants who were born in Dr. Cipto Mangunkusumo Hospital during the period between September 2014 and June 2016 had birth defects. Forty-seven (70.1%) mothers of the subjects irregularly attend antenatal care. The most frequent maternal comorbid disease in this study was asthma, which was found in 4 (5.97%) mothers of the subjects. 48 (58.7%) subjects had birth weight under 2500 g.

Conclusion: In this retrospective study, the main highlight is that 70.1% of the mothers who delivered neonates with birth defects did not attend antenatal care regularly. 58.7% of the neonates with birth defects had low birth weight. This study could be used as a base for further research investigating the role of antenatal care in early detection and/or the planning of delivery for babies with birth defects.

Keywords: birth defect, maternal characteristics

Abstrak

Tujuan: Untuk mengetahui deskripsi/ciri-ciri dan latar belakang ibu yang melahirkan janin dengan kelainan bawaan.

Hasil: Sejumlah 67 (1,85%) dari 3,619 neonatos didapatkan dengan kelainan bawaan di RSUPN Dr. Cipto Mangunkusumo pada periode September 2014-Juni 2016. Sejumlah 47 (70,1%) ibu dari subjek tidak teratur dalam melakukan kunjungan antenatal care. Penyakit komorbid ibu yang paling banyak ditemukan dalam studi ini adalah astma, yang ditemukan dalam 4 (5,97%) subjek. 48 (58,7%) subjek memiliki berat lahir di bawah 2500 g.

Kesimpulan: Pada studi retrospektif ini didapatkan 70,1% ibu yang melahirkan bayi dengan kelainan bawaan tidak melakukan kunjungan antenatal care. Ditemukan bahwa 58,7% bayi yang lahir dengan kelainan bawaan memiliki berat lahir rendah (BBLR). Studi ini dapat dipandang sebagai landasan dilakukannya studi yang lebih besar untuk mengevaluasi peran antenatal care terhadap deteksii dan/atau perencanaan persalinan bayi dengan kelainan bawaan. Tren pada bayi dengan kelainan bawaan menunjukkan bahwa bayi yang pada antenatal care didapatkan IUGR/SGA patut diperhatikan lebih untuk kecurigaan kemungkinan adanya kelainan bawaan.

Kata kunci: deskripsi ibu, kelainan bawaan

Birth defects affect 3% of all neonates, cause 3.2 million birth defect-related disabilities, and result in 2.7 million infant deaths.\textsuperscript{8} They have a significant effect on individuals, families, health-care systems and societies. Birth defects are particularly serious health burden in low- and middle-income countries, including Indonesia, due to consanguineous marriage, advanced maternal age, migration and poverty.

The magnitude of birth defects varies from country to country and from race/ethnicity, and about 40-60% of their causes are unknown.\textsuperscript{9} According to the World Health Organization, approximately 3 million fetuses and infants are born each year with major malformations.\textsuperscript{2} Approximately 94% of infants born with birth defect were reported to come from the middle and low-income countries, and it also recorded 95% of the death of such children from birth defects.\textsuperscript{10} The defects pose serious psychological stress or nursing mothers due to potential life-long disability.\textsuperscript{11}

Studies describing maternal characteristics associated with birth defects have never been conducted in Indonesia. We aim to describe the characteristics of mothers who give birth to infants with birth defects.

\textbf{METHODS}

A retrospective study design was used by evaluating the medical records of patients with birth defects in Dr. Cipto Mangunkusumo Hospital during the period between September 2014 and June 2016. Inclusion criteria include subjects with spina bifida, anencephaly, meningoencephalocele, congenital cataract, cleft palate, cleft lip, cleft lip and palate, hypospadias, epispadias, talipes, reduction deformity, atresia ani with/without fistula, omphalocele, gastroschisis, or conjoined twins.

\textbf{RESULTS}

Sixty-seven (1.85\%) out of 3,619 neonates born at Dr. Cipto Mangunkusumo Hospital during the period between September 2014 and June 2016 had birth defects. Six (9\%) mothers of the subjects were Javanese. Fifteen (22.39\%) mothers of the subjects resided in East Jakarta. Forty-seven (70.1\%) mothers of the subjects irregularly attend antenatal care. Demographic characteristics of the subjects are presented in Table 1.

Types of delivery
- Caesarean section: 42 (63%)
- Spontaneous: 25 (37%)

Gestational age
- < 37 weeks: 40 (60%)
- ≥ 37 weeks: 27 (40%)

Maternal comorbid disease
- Asthma: 4 (5.97%)
- Diabetes: 1 (1.49%)
- Graves’ disease: 2 (2.99%)
- Others*: 4 (5.97%)
- Denied: 43 (64.18%)
- Unknown: 13 (19.40%)

*Others = severe preeclampsia, primary infertility, thyroid carcinoma, uterine myoma

In this study, the commonest birth defect was omphalocele (20.48%), followed by labiogнатo-palatochizis (9.64%), talipes (9.64%), and others consisting of anencephaly, atresia ani, as well as conjoined twins (8.43%). Defects related to gastrointestinal system (29.79%) were the commonest, followed by central nervous system (19.7%), and facial and oral malformations (13.64%). The occurrence of multiple organ defects was 18.18%. Forty-two (63%) mothers of the subjects underwent caesarean section. Forty (60%) mothers had gestational ages below 37 weeks. Four (5.97%) mothers of the subjects had asthma in this study.

The percentage of each birth defect based on organ system were respectively as follow. The percentage of defects related to central nervous system including anencephaly, encephalocele, meningoencephalocele, ventriculomegaly, and spina bifida was 38.89%, 5.56%, 16.67%, 5.56%, and 33.33%, respectively. The percentages of defects related to gastrointestinal system including omphalocele, gastroschisis, and atresia ani, were 60.71%, 14.29%, and 25%, respectively. Musculoskeletal defects including talipes, limb shortness, hypoplasia of the extremities, and amelia were 57.14%, 28.57%, 7.14%, and 7.14%, respectively. Genitourinary defect including hypospadias was 5.97%. The percentages of other birth defects consisting of congenital cataract and conjoined twins were 12.5% and 87.5%.

Of 67 subjects, 19 were excluded due to the lack of ultrasound findings. Of 48 subjects, 36 (75%) of prenatal ultrasound findings were matching with postpartum findings.

**Figure 1.** The incidence of intrauterine fetal death (IUFD) and neonatal death.
The majority of the newborns were female (52.3%). 58.7% of the subjects had low birth weight (<2500 g). The mean birth weight of newborns was 2236.98 ± 792.92. The lowest and highest birth weights were 600 g and 3880 g, respectively. The incidence of intrauterine fetal death (IUDF) and neonatal death in their first 28 days of life were 7.46% and 32.8%, respectively (Figure 1).

DISCUSSION

Regularity of Antenatal Care Visits

Antenatal care is a crucial element for improving maternal and neonates health. Effective antenatal care improves maternal health through early detection, prevention as well as treatment of medical and obstetrical complications during pregnancy. In this study, 40 (70.1%) mothers of the subjects irregularly attend antenatal care, which suggested that the regularity of antenatal care visits might be a key element in preventing birth defects. However, to our knowledge, studies investigating the association between regularity of antenatal care visits and the occurrence of birth defects have never been conducted. A possible explanation is that mothers who irregularly attend antenatal care have lower knowledge about the prevention of birth defects, which may lead to high incidence of birth defects. Further studies are required to investigate this association.

Maternal Educational Level

In this study, no direct association between maternal educational level and the occurrence of birth defects were found. This is in line with a previous study conducted by Bello et al which revealed that the level of education had no significant relationship with their specific knowledge, knowledge in relation to risk factors and the overall knowledge about birth defect.

Maternal Age

In this study, maternal age above 35 years old had no direct association with the occurrence of birth defects. This is contrary to previous studies, which might be due to smaller population size. Hollier et al concluded that increased maternal age was significantly associated with chromosomal aberrations, particularly aneuploidies. In addition, it has been reported that woman who were 25 years of age or older at delivery had significantly and progressively greater risk of having fetuses with non-chromosomal malformation compared to women aged 20-24 years. The National Center for Health Statistics conducted a study about the effects of advanced maternal age on risks of congenital malformations. These data demonstrated a significant trend of increasing congenital heart disease with advancing maternal age. However, infants with chromosomal abnormalities were not considered separately in that study.

Gestational Age

In this study, 60% of the subjects had gestational age less than 37 weeks. This showed that the occurrence of birth defects is higher in the premature population. This finding is in line with several previous studies. In a population-based cohort study of 264,392 infants, 7,738 (2.93%) were identified as having birth defects. The study revealed that premature infants were more than two times as likely to develop birth defects (risk ratio [RR] = 2.43; 95% CI 2.30-2.56).

Maternal Comorbid Disease

The most frequent maternal comorbid disease in this study was asthma (5.97%). This is in line with a previous study conducted by Blais et al which found that maternal asthma was significantly associated with an increased risk of congenital malformation. This might be due to impaired fetal oxygenation and medications used to treat asthma. A systematic review and meta-analysis of 21 studies found that maternal asthma was associated with a significantly increased risk of congenital malformations (RR 1.11, 95% CI 1.102-1.21).

Prenatal Ultrasound and Postpartum Findings

Prenatal ultrasound was established in Russia in 2000 as a routine method of screening for birth defects. The effectiveness of prenatal screening can be estimated by the prenatal detection rate, which represents the proportion of birth defects recognised before delivery. The sensitivity and specificity of ultrasound were 39% and 99.9%, respectively. Several birth defects can be identified accurately based solely on prenatal findings. Exam-
Birth Weight

In this study, the majority of the subjects had birth weight <2500 g. This finding is in line with previous studies. In a cohort of 307 fetuses with congenital heart diseases, 17% were associated with a birth weight centile <10th when standard population centiles were used. The Baltimore-Washington Infant Study suggested that, in infants with CHD, birth weight was significantly lower than the control population. Mili et al found that low-birth-weight infants were at a 1.76-times higher risk of having birth defects than those weighing 2500 g to 3999 g.

Postnatal Treatment

Neonatal screening for birth defects may facilitate early detection, treatment and care. Neonatal screening programmes (physical examination of all neonates and screening for congenital hypothyroidism, phenylketonuria, sickle-cell disease and glucose-6-phosphate dehydrogenase deficiency) and training of primary health-care providers aids the diagnosis and appropriate referral for treatment of infants with birth defects. Physical examination of all neonates by trained primary health-care practitioners is feasible in most health care centres and allows the identification of numerous birth defects, including cardiovascular defects that are associated with a high risk of early mortality and referral.

CONCLUSION

In this retrospective study, the main highlight is that 70.1% of the mothers who delivered neonates with birth defects did not attend antenatal care regularly. 58.7% of the neonates with birth defects had low birth weight. This study could be used as base for further research investigating about the role of antenatal care in early detection and/or the planning of delivery for babies with birth defects. Trends in babies with birth defects suggested that fetuses diagnosed with IUGR/SGA should be given special attention, as they were at increased risk for birth defects.
